Measurement of Higgs branching ratio is necessary to investigate Higgs coupling to particle masses. Especially, it is the most important program to measure the branching ratio of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ at the international linear collider (ILC). We have studied the measurement accuracy of Higgs branching ratio at ILC with $\sqrt{s} = 250$ GeV by using $ZH \rightarrow \nu\bar{\nu}H$ events. We obtained the Higgs branching ratio with 1.1% and 13.7% accuracy for $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$, respectively.

1 Introduction

In the Higgs mechanism, Higgs coupling is proportional to a particle mass. For that reason, it is important to measure the Higgs coupling to particle masses, i.e. Higgs branching ratio, is important to confirm Higgs mechanism and distinguish the Standard Model extensions. Especially, it is the most important program to measure the branching ratio of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ at ILC [1] with the excellent performance of the flavor tagging.

We have studied the measurement accuracy of Higgs branching ratio at ILC by using $ZH \rightarrow \nu\bar{\nu}H$ events. In this paper, we report the measurement accuracy of Higgs branching ratio of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$.

2 Simulation tools

In this study, we used common generator samples in the ILC community for ZH events and standard model backgrounds, which were prepared with WITHERD at SLAC [2]. In this study, the Higgs mass was assumed to be 120 GeV. We used the center of mass energy of $\sqrt{s} = 250$ GeV and the integrated luminosity of 250 fb^{-1} . Here, the beam energy spread was assumed as 0.3% for the electron and positron beam. The beam polarization was set to 80% left-handed for the electron beam and 30% right-handed for the positron beam.

The signal and background events were simulated by the full simulator, Mokka[3], where the detector model is ILD_00 was implemented as the detector model [4]. Hadronization was done by Pythia6.409, in which the Higgs branching ratio is defined as shown in Table 2 for the Higgs mass of 120 GeV. After the detector simulation, the reconstruction was performed by Marlin[5].

	Branching ratio
$b\bar{b}$	65.7%
W^+W^-	15.0%
$\tau^+\tau^-$	8.0%
$g\bar{g}$	5.5%
$c\bar{c}$	3.6%

3 Event selection

In this study, the final states of four fermions are considered as background events, where they are classified into 6 groups, $\nu\nu qq$, $qqqq$, νlqq , $llqq$, $\nu\nu ll$ and $llll$. The signal and background events are summarized in Table 2. All events are reconstructed as 2-jet events by Durham jet algorithm [6]. By using the reconstructed 2 jets, the di-jet mass (M_{jj}) was reconstructed as shown in Fig. 1. Since the background events dominate in the Higgs mass region, the selection cuts were investigated.

At first, we studied the distribution of missing mass (M_{miss}). Since a Z boson decays into the neutrino pair in $ZH \rightarrow \nu\bar{\nu}H$ events, the missing mass should be consistent with Z boson mass (91.2 GeV). We, therefore, selected the events with $80 \text{ GeV} < M_{\text{miss}} < 140 \text{ GeV}$. Applying this cut, $llll$, $llqq$, and $qqqq$ events were suppressed. Then, we required that the reconstructed di-jet particles have the transverse momentum (p_T) from 20 to 70 GeV and longitudinal momentum (p_L) below 60 GeV. We selected the number of charged tracks (N_{tracks}) above 10 to remove $W^+W^- \rightarrow l^+\nu l^-\bar{\nu}$ events.

After the selection cuts so far, $\tau\nu_\tau qq$ events become the main background. The maximum track momentum in each events (p_{max}) were investigated since the charged tracks from τ have relatively higher momentum than those from b -jets. We selected the events with $p_{\text{max}} < 30 \text{ GeV}$. Y_+ is the threshold y -value to reconstruct 2-jet as 3-jets. Since the final state of $ZH \rightarrow \nu\bar{\nu}q\bar{q}$ and $\tau\nu_\tau qq$ is 2 and 3 bodies, respectively, Y_+ for $ZH \rightarrow \nu\bar{\nu}q\bar{q}$ events has smaller value than $\tau\nu_\tau qq$ events. On the other hand, Y_- , the y -value to reconstruct 2-jet as 1-jets, has larger value for $ZH \rightarrow \nu\bar{\nu}q\bar{q}$ events than $\nu\bar{\nu}qq$ and $lvqq$ because β of W and Z bosons from decay of WW and ZZ events is larger than Higgs from $ZH \rightarrow \nu\bar{\nu}q\bar{q}$. We, therefore, selected $Y_+ < 0.02$ and $0.2 < Y_- < 0.8$.

Finally, the signal region was set to be $100 \text{ GeV} < M_{jj} < 130 \text{ GeV}$. After all the selection cuts, $\nu\nu qq$ events from WW and ZZ events were reduced as shown in Fig. 2. The number of signal and background events and the selection efficiencies after the selection cut was summarized in Table 2.

Figure 2: Distribution of the reconstructed di-jet mass after the selection cuts for signal (left) and background (right).

	cross section (fb)	No. of events	No. of events after all cuts	Efficiency (%)
ZH	77.4	19,360	7,384	38.14
$ZH \rightarrow \nu\bar{\nu}bb$	52.2	13,062	6,434	49.26
$ZH \rightarrow \nu\bar{\nu}c\bar{c}$	2.83	707	318	44.98
$\nu_e e qq$	5843.2	1,460,797	851	0.06
$\nu_\mu \mu q$	5309.3	1,327,332	2,288	0.17
$\nu_\tau \tau q$	5304.2	1,326,061	24,979	1.88
$\nu_\nu qq$	599.9	149,979	21,653	14.44
Other	25291	6,322,758	335	0.01

4 Measurement of Higgs branching ratio

To measure the Higgs branching ratio of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$, the template fitting was performed [7]. For the template fitting, 3-dimensional histogram for the b -, c -, and bc -likeness was used, which are obtained as output values from LCFIVertex package [8]. In LCFIVertex, neural-net training was done by using $Z \rightarrow qq$ events at Z -pole (91.2 GeV) to derive b - and c -likeness. bc -likeness is c -likeness whose neural-net training is done by using only $Z \rightarrow bb$ events as background. The each flavor-likeness for two jets are combined as,

$$X\text{-likeness} = \frac{X_1 \cdot X_2}{X_1 \cdot X_2 + (1 - X_1)(1 - X_2)} \quad (1)$$

where $X = b, c$ or bc . X_1 and X_2 are the flavor-likeness of the first and second jet, respectively.

The template sample is separated into $H \rightarrow b\bar{b}$, $H \rightarrow c\bar{c}$, $H \rightarrow other$, and Standard Model background events. Figure 3 shows the 2-dimensional template histogram for b -likeness and

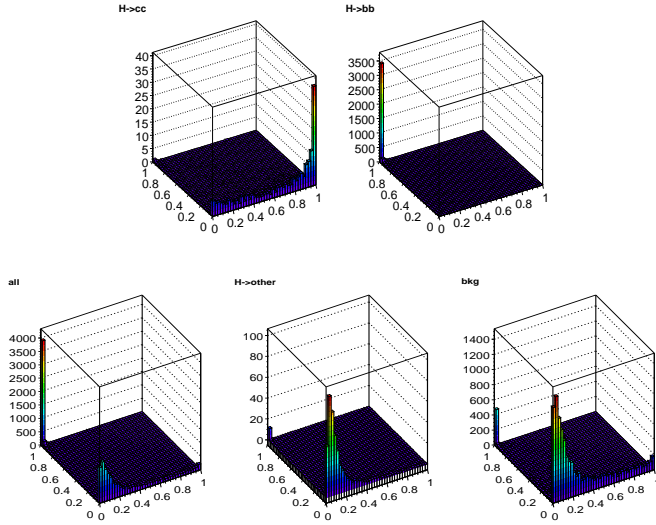

Figure 3: 2-dimensional template histogram for b -likeness and c -likeness.

c -likeness. In $H \rightarrow other$ sample, $H \rightarrow gg$ and $H \rightarrow W^-W^+$ events are dominant. Since the both distributions are identical, they are treated in one template sample.

In the template fitting, the fitting parameters (r_{bb} , r_{cc} , r_{oth} , and r_{bkg}) were adjusted to minimize the following χ^2 function:

$$\chi^2 = \sum_{i=1}^{n_b} \sum_{j=1}^{n_c} \sum_{k=1}^{n_{bc}} \frac{(N_{ijk}^{data} - \sum_s r_s (\frac{N^{ZH}}{N^s}) N_{ijk}^s - r_{bkg} N_{ijk}^{bkg})^2}{N_{ijk}^{all}}, \quad (2)$$

where s shows $b\bar{b}$, $c\bar{c}$ and $other$. r_{bb} , r_{cc} , r_{oth} are the fraction of $H \rightarrow b\bar{b}$, $H \rightarrow c\bar{c}$, $H \rightarrow others$ in ZH events after the selection cut, where we set $r_{other} = 1 - r_{cc} - r_{bb}$. r_{bkg} is the normalization factor of the Standard Model background. N_{ijk}^s are the number of expected events in (i, j, k) bin of the 3-dimensional histogram.

To estimate the reconstruction accuracy of r_{bb} and r_{cc} , the fitting was done for 1,000 times by using Toy-MC. Figure 4 shows the distributions of r_{bb} and r_{cc} obtained by the fitting. r_{bb} and r_{cc} were determined to be 0.87 ± 0.01 and 0.046 ± 0.009 , respectively. These mean values are consistent with the true r_{bb} (0.87) and r_{cc} (0.046). From the result, if the cross section of $e^+e^- \rightarrow ZH$ can be determined with other measurements like a measurement of the Higgs recoil mass [9] and the selection efficiencies of $ZH \rightarrow \nu\bar{\nu}b\bar{b}$ and $ZH \rightarrow \nu\bar{\nu}c\bar{c}$ are known, Higgs branching ratio of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ can be measured with accuracy of 1.1% and 13.7%, respectively.

To evaluate the influence of Standard Model background on determination of the Higgs branching ratio, we performed the template fitting, fixing r_{bkg} to 1. r_{bb} and r_{cc} were determined to be 0.87 ± 0.01 and 0.046 ± 0.006 , respectively. It corresponds to the measurement accuracy of 1.1% and 13.6% for r_{bb} and r_{cc} , respectively. From this result, it was found that

	r_{bkg} : free	$r_{bkg} = 1$
BR($H \rightarrow b\bar{b}$)	1.1%	1.1%
BR($H \rightarrow c\bar{c}$)	13.7%	13.6%
BR($H \rightarrow c\bar{c}/H \rightarrow b\bar{b}$)	13.3%	13.3%

Table 3: The measurement accuracy of Higgs branching ratio. For measurement accuracy of BR($H \rightarrow b\bar{b}$) and BR($H \rightarrow c\bar{c}$), it is assumed that the cross section of ZH is determined by other measurements.

the fluctuation of the background normalization has only negligible effects on the measurement of Higgs branching ratio.

Without any other measurement, we can measure the relative branching ratio between $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ by analysis of only $ZH \rightarrow \nu\bar{\nu}H$ events as follows:

$$\frac{BR(H \rightarrow c\bar{c})}{BR(H \rightarrow b\bar{b})} = \frac{r_{cc}/\epsilon_{cc}}{r_{bb}/\epsilon_{bb}}, \quad (3)$$

where ϵ_{bb} and ϵ_{cc} are the selection efficiencies of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ events as shown in Table 2. The relative branching ratio of 0.054 ± 0.007 was obtained for the template fitting with free and fixed r_{bkg} , which corresponds to 13.3% accuracy. The measurement accuracy for Higgs branching ratio is summarized in Table 3.

5 Conclusion

Measurement of Higgs branching ratio is necessary to investigate Higgs coupling to particle masses. Especially, it is the most important program to measure the branching ratio of $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ at ILC. We have studied the measurement accuracy of Higgs branching ratio at ILC with $\sqrt{s} = 250$ GeV by using $ZH \rightarrow \nu\bar{\nu}H$ events. For Higgs mass of 120 GeV and the integrated luminosity of 250 fb^{-1} , we obtained the measurement accuracy of 1.1% and 13.7% for $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$, respectively, assuming that the cross section of ZH is determined by other measurements. Finally, the relative branching ratio between $H \rightarrow b\bar{b}$ and $H \rightarrow c\bar{c}$ was obtained with 13.3% accuracy.
